Develop a program using Python that simulates the behaviour of the SQL command SELECT using command-line arguments. The output is expected to be displayed in a properly formatted tabular form.

The program should read data from an input table stored as a **.csv file**. This CSV file represents a database table and must be accessed and processed through the program to simulate the SELECT command.

SELECT commands to be simulated:

a. `SELECT * FROM students`
b. `SELECT * FROM students WHERE CGPA > 8`
c. `SELECT Name, CGPA FROM students`

The input table ***students (Roll No, Name, Department, CGPA, Age)***, stored as a CSV file, must contain at least 10 records. The entire SELECT command should be provided as a single command-line argument while executing the program. The program is expected to parse the command, apply the appropriate selection and/or filtering logic on the CSV data, and display the resulting output in a properly formatted tabular form. The input table may be created either manually (directly as a CSV file) or programmatically through code.

NOTE: The `SELECT` command in SQL is used to retrieve data from a database table. It allows users to display all columns using * or specify individual column names, in which case only the mentioned columns are printed. The command can also include a `WHERE` clause to filter rows based on given conditions, enabling efficient querying of stored data.
